Concept Definitions and Maps for Electric Circuits

Hu Hanrahan Emeritus Professor, School of Electrical and Information Engineering, University of the Witwatersrand, Johannesburg Hu.hanrahan@wits.ac.za

Revised 13 June 2017

Introduction

The paper A Conceptual Framework for Electric Circuits [Ref] provides a set of definition of the concepts and maps these to answer the *focus question*:

What is circuit theory and analysis that serves as a foundation for much of electrical engineering?

for the case of resistive circuits, that is, circuits containing sources and resistors.

Assumed prior knowledge from Physics is defined in the paper and is supplemented under the definitions in response to Q6 below.

The focus question is addressed via eight subsidiary questions, each corresponding to a group of related concepts. The first five questions are addressed in the paper and the concept definitions and concept maps are repeated below:

- <u>Q1</u>: What are the physical origins of electric circuit variables and elements?
- <u>Q2:</u> What are the circuit elements and variables and what is their behavior?
- <u>Q3:</u> What are the fundamental laws and principles of circuit analysis?
- <u>Q4:</u> What are the principles and methods of analysis of a circuit as a system by simplifying parts or the whole circuit?
- <u>Q5:</u> What are the principles and methods of analysis of a circuit as a system by systematically setting up equations for solution?

The remaining three questions are addressed in this document, namely:

- <u>Q6:</u> What are the physical basis and behavior as circuit elements of <u>(a) capacitors</u> and <u>(b)</u> <u>inductors</u>?
- <u>Q7:</u> What is the behavior and analysis method for circuits containing resistors, capacitors and inductors with time-varying sources?
- <u>Q8:</u> What is the behavior and analysis method for circuits containing resistors, capacitors and inductors under sinusoidal steady state conditions?

The figure below maps the groups of concepts that emerge in response to these questions. Such groups of concepts are referred to as *segments* of the knowledge base.

An <u>estimate of the size of the knowledge base</u> is given in terms of the number of concepts and links between concepts.

This navigation bar is placed at the end of each question:

<u>Top</u>	<u>Q1</u>	<u>Q2</u>	<u>Q3</u>	<u>Q4</u>	<u>Q5</u>	<u>Q6-C</u>	<u>Q6-L</u>	<u>Q7</u>	<u>Q8</u>

Repeat of Figure 2 in paper: High level concept map addressing the focus question

Question 1: Physical origins of electric circuit variables and elements

Table II: Concepts for Q1: What are the physical origins of electric circuit variables and elements?

- **PK:** Matter is made up of atoms that contain a dense nucleus consisting of positively charged protons and neutrons with negatively charged electrons, equal in number to the protons in the nucleus. Electrons occupy orbitals with discrete energy levels. The numbers of protons and neutrons are unique to the element and determine its position in the periodic table. The highest energy level electrons are valence band electrons; they determine how atoms of an element bond with each other and with other elements. Mechanical concepts including force, energy and work are also assumed known
- **C01: Electric charge** or **charge** for the purpose of circuit analysis is a population of <u>electrons</u> (defined as negative) or of <u>protons</u> (defined as positive), or, in a structure such as a battery, positive or negative ions
- **C02: Conservation of charge** is a physical principle that states that in any process involving <u>charges</u>, no net charge is created or destroyed.
- **C03: Solid matter** has <u>atoms</u> in a fixed arrangement (lattice); at temperatures of interest, atoms vibrate in the lattice
- **C04:** Free electrons, or conduction [band] electrons, are <u>electrons</u> with sufficient energy to become freed from the <u>valence band</u> of the parent atom; where a valence electron has been freed, the parent atom becomes a positive ion with a net charge of one proton
- **C05:** A **conducting material (conductor)** is a [solid] material that has <u>free electrons</u> that can move through the material if energy is imparted; conductor is also applied to a piece of conducting material
- **C06:** A dielectric is a material with negligible concentration of <u>free electrons</u> that therefore does not allow charge to move through it

- **C07: Electrical force** between **charges** depends on <u>the spatial distribution of the charges</u> and their signed magnitudes, like charges repelling and unlike charges attracting, and the medium in the surrounding space
- **C08:** An **electric field** in the vicinity of concentration(s) of charge represents the spatial variation of the magnitude and direction of the <u>electrical force</u> experienced by a unit test charge in the space
- **C09:** [Electrical] **potential energy** is the work that has to be done against the <u>forces between</u> <u>charges</u> to bring about a given arrangement of <u>charges</u>
- C10: Voltage is the difference in potential energy between two identified points in a circuit
- C11: Current is the rate of flow of <u>charge</u> in a defined cross section
- **C12: Conventional current** is the generally adopted convention that <u>current</u> in a chosen direction is positive if positive charge is moving in that direction or negative charge is moving in the opposite direction
- **C13: Resistivity** is a property of a <u>conducting material</u> that determines the relationship between the resulting <u>current</u> per unit area (current density) and the <u>electric field</u> in the material
- **C14: Resistance** is a property of a device made of <u>conducting material</u> quantifying the propensity for the conductor to resist the flow of <u>current</u> when a <u>voltage</u> is applied or exists across the terminals
- **C15: Temperature coefficient of resistivity** quantifies the way that the <u>resistivity</u> of a conducting material (and hence the resistance of a conductor) changes with temperature, linearly in many cases
- **C16:** A **resistor** is a device made of a conducting material, exhibiting <u>resistance</u> between its two terminals
- **C17: Ohm's Law** is a linear relationship between <u>voltage</u> across and <u>current</u> in a <u>resistance</u>; the proportionality constant is the <u>resistance</u> value
- **C18:** A **circuit element** is a self-contained device or representation which has a characteristic relationship between <u>current</u> through the element and <u>voltage</u> between the terminals
- **C19: Circuit variables** are quantities, including <u>voltage</u> and <u>current</u> that describe the predicted or observed behaviour of the circuit
- **C20:** An **electric circuit** or **electrical network** is a set of interconnected <u>circuit elements</u> whose behaviour is observed via <u>circuit variables</u>

Fig 3: Concept map for the question: Q1: What are the physical origins of circuit variables and elements?

Top	<u>Q1</u>	<u>Q2</u>	<u>Q3</u>	<u>Q4</u>	<u>Q5</u>	<u>Q6-C</u>	<u>Q6-L</u>	<u>Q7</u>	<u>Q8</u>

Question 2: Circuit elements and variables and their behavior

Table III: Concepts for Q2: What are the circuit elements and variables and what is their behavior?

- **C21: Conservation of energy** holds in a self-contained <u>electric circuit</u>: energy may be converted to heat or stored but not created or destroyed.
- C22: Energy in an <u>electric circuit</u> is the work done in moving <u>charge</u> (in the form of <u>current</u>) through a potential difference (<u>voltage</u>)
- **C23: Power** in an electric circuit is the rate of change or flow of <u>energy</u> given at any instant by the product of <u>current</u> and <u>voltage</u>
- **C24:** The **power converted to heat** in a resistor with resistance *R* at any instant is the product of the voltage (v) across its terminals and the current (*i*) through it or, from Ohms Law, $i^2 R$
- **C25:** A **[sign] convention** for a <u>circuit variable</u> is a method of defining a possibly unknown circuit variable (voltage, current, power, energy), including arbitrarily allocating a positive sign or direction for use in circuit analysis and reconciliation with actual values that may be given or emerge from calculations or measurements
- **C26:** A **waveform** is a description of the variation of a <u>circuit variable</u> with time, usually as an equation or graphically
- **C27:** The **average value** of a <u>waveform</u> is a single figure measure for a circuit variable calculated over a specified period by dividing the integral of the waveform over the period by the period

C28: The **root mean square** value of a <u>waveform</u> is a single figure measure calculated over a specified period by dividing the integral of the squared waveform over the period by the period and taking the square root of the result

C30: An **ideal [independent] voltage source** is a <u>circuit element</u> that maintains a stated <u>voltage</u> (which may vary with time) across its terminals independent of the <u>current</u> at its terminals.

- **C31:** An **ideal [independent] current source** is a <u>circuit element</u> that maintains a stated <u>current</u> (which may vary with time) at its terminals independent of the voltage across its terminals.
- **C32:** An **ideal dependent voltage source** is a <u>circuit element</u> that maintains a <u>voltage</u> across its terminals that is proportional to a control variable, which may be either a <u>voltage</u> or <u>current</u> that may vary with time, independent of the current at its terminals.
- **C33:** An **ideal dependent current source** is a <u>circuit element</u> that maintains a <u>current</u> at its terminals that is proportional to a control variable, which may be either a <u>voltage</u> or <u>current</u> that may vary with time, independent of the voltage across its terminals.
- **C34:** An **active [circuit] element** is a <u>circuit element</u> that is able to supply <u>energy</u> when connected in a circuit
- **C35:** A **passive [circuit] element** is a <u>circuit element</u> that when supplied with <u>energy</u> either converts it to heat or stores it; stored energy may be returned.
- **C36:** An **open circuit** is a hypothetical <u>circuit element</u> that exists between two terminals that allows no flow of <u>current</u> and can be treated in circuit analysis as an infinite <u>resistance</u> between the terminals
- **C37:** A **short circuit** between two terminals is effectively a zero<u>resistance</u> and the <u>current</u> flowing is determined by the remainder of the circuit between the terminals

Fig 4: Concept map for the question: Q2: What are the circuit elements and variables and what is their behavior?

Question 3: Fundamental laws and principles of circuit analysis

Table IV: Concepts for Q3: What are the fundamental laws and principles of circuit analysis?
C40: A node is a point in a circuit at which the terminals two or more <u>circuit elements</u> connect; the connecting conductors are assumed to have negligible <u>resistance</u> and the node does not accumulate <u>charge</u>.
C41: A branch is formed by a single <u>element</u> between two <u>nodes</u>; the <u>current</u> entering one node always equals the current leaving the other.

- **C42:** A **[closed] loop** in a circuit is path containing a set of <u>circuit elements</u> connected end to end at <u>nodes</u> returning to the chosen starting node and encountering each node only once
- C43: A planar circuit is one that is possible to draw with no branches crossing
- C44: A mesh is a region of a <u>planar circuit</u> bounded by <u>branches</u> with no branches crossing the region
- C45: The system view or behaviour of a <u>circuit</u> is the analysis and solution of the circuit that accounts for the collective behaviour of the <u>elements</u> that make up the circuit
- **C46: Kirchhoff's Voltage Law** states that the sum of the <u>voltages</u> defined in a consistent direction around a <u>closed loop</u> in a circuit is zero; this law is based on the principle of conservation of energy
- **C47: Kirchhoff's Current Law** states that at a <u>node</u> in a circuit, the algebraic sum of the <u>currents</u> entering the node is zero; this law is based on the principle of conservation of charge
- **C48: Solution by simplification**: any method, based on <u>Kirchhoff's Laws</u>, of analysing and solving for selected unknown <u>voltages</u> or <u>currents</u> by reducing the complexity of parts of the circuit where each reduced form preserves the system behaviour of the resulting circuit
- **C49: Systematic solution:** any method, based on <u>Kirchhoff's Laws</u>, for analysing and solving for unknown <u>voltages</u> or <u>currents</u> by setting up sufficient simultaneous equations to allow unknown variables in the circuit to be found

Question 4: Principles and methods of analysis of a circuit as a system by simplification

Table V: Concepts for Q4: What are the principles and methods of analysis of a circuit as a system by simplifying parts or the whole circuit?

- **C50:** The **equivalent circuit** for a set of interconnected <u>circuit elements</u> with identified terminal <u>nodes</u> is a different set of elements that, if connected at the same set of terminal nodes to an external circuit, would result in the same <u>voltages</u> and <u>currents</u> at those nodes.
- **C51: Resistor network** is a set of <u>resistors</u> connected together with specified <u>nodes</u> that may connect to an external circuit at those nodes.

C52: <u>Circuit elements</u> **connected in series** are connected end to end at intervening <u>nodes</u> with no other <u>branch</u> connected to any intervening node; all elements have the same value of <u>current</u>

C53: The **equivalent resistance of resistors** in series is a single <u>resistor</u> with <u>resistance</u> equal to the sum of the individual resistances

- **C54:** The **voltage divider rule** relates the <u>voltage</u> across one of two <u>series resistors</u> to the voltage across the combination
- **C55:** <u>Circuit elements</u> are **connnected in parallel** if their respective opposite <u>nodes</u> are connected at two nodes; all elements have the same value of <u>voltage</u>
- **C56:** The **equivalent resistance of resistors in parallel** is a single <u>resistor with resistance</u> with reciprocal equal to the sum of the reciprocals of the individual resistors
- **C57:** The **current divider rule** relates the <u>current</u> in one of two <u>parallel resistors</u> to the terminal current of the combination
- **C58:** Three <u>circuit elements</u> of the same type are **star-connected** if one <u>node</u> of each is connected to form a common node; the remaining three nodes may be connected to an external network
- **C59:** Three <u>circuit elements</u> of the same type are **delta-connected** if connected end to end to form a <u>closed loop</u>; the three <u>nodes</u> at which pairs of elements connect may be connected to an external network
- **C60:** Star-delta transformation allows three <u>resistors</u> connected in one form, say <u>star</u>, to be replaced by the other form, say <u>delta</u>, and conversely, while not affecting the behaviour of an external circuit connected to the three terminals
- **C61: Redundant circuit elements** are those that may be removed from a given circuit without affecting <u>voltages</u> or <u>currents</u> of interest in the remainder of the circuit
- C62: Interconnected ideal sources may in some cases be simplified to an equivalent circuit
- **C63: An intractable circuit** is one in which the characteristics of interconnected sources are incompatible and preclude analysis
- **C65:** A **two-terminal network** is a network of arbitrary complexity with all control variables for <u>dependent sources</u> within the network that has two <u>nodes</u> only at which external connections may be made
- **C66: Thévenin's Theorem** states that an arbitrarily complex, <u>two-terminal network</u> has an <u>equivalent circuit</u> consisting of an <u>ideal voltage source in series</u> with a <u>resistor</u>
- **C67: Norton's Theorem** states that an arbitrarily complex, <u>two-terminal network</u> has an <u>equivalent circuit</u> consisting of an <u>ideal current source</u> in <u>parallel</u> with a <u>resistor</u>
- **C68: Source transformation** is based on fact that <u>Thévenin</u> and <u>Norton equivalent circuits</u> are <u>equivalent circuits</u> of each other and one form may be replaced by the other
- **C69: Open circuit and short circuit tests** (or analysis) are methods of finding respectively the <u>Thévenin</u> voltage and <u>Norton</u> current values of a two-terminal network
- **C70:** The **equivalent resistance of an unexcited two-terminal network** determined with all <u>independent source</u> values set to zero (unexcited) is equal to the <u>resistance</u> of the <u>Thévenin</u> <u>equivalent</u> of the network
- **C71:** A variable load test is a method of determining <u>Thévenin equivalent</u> circuit parameters; the terminal <u>voltage</u> as the external <u>resistor</u> (load) tends to infinity is the Thévenin voltage and the load <u>resistor</u> that halves the output voltage relative to the open circuit voltage is equal to the Thévenin resistance
- **C72:** The **Maximum Power Transfer Theorem** states that to transfer maximum <u>power</u> from a two-terminal resistive network to a load resistor, the load <u>resistance</u> must be equal to the Thévenin resistance of the network

Fig 6: Concept map for the question Q4: What are the principles and methods of analysis of a circuit as a system by simplifying parts or the whole circuit?

Question 5: Principles and methods of systematic analysis of a circuit

- **Table VI: Concepts for Q4:** What are the principles and methods of analysis of a circuit as a system by systematically setting up equations for solution?
- **C76:** A **reference node** or **datum node** is a <u>node</u> assigned a <u>voltage</u> of zero as reference for measuring the voltages of all other nodes
- **C77:** A **supernode** is an interconnected portion of a network consisting of two or more nodes with independent or dependent <u>voltage source(s) between the nodes</u>
- **C78:** Nodal analysis, or node-voltage analysis develops equations for the <u>node voltages</u> relative to the <u>reference node</u> to solve a circuit by applying <u>Kirchhoff 's current law</u> at nodes (other than than nodes in supernodes) and <u>supernodes</u> in the circuit
- **C79:** A **supermesh** is a group of two or more adjacent <u>meshes</u> having common <u>branches</u> containing <u>independent</u> or <u>dependent current sources</u>
- **C80:** Mesh analysis, or mesh current analysis develops equations for currents defined around <u>meshes</u> to solve a circuit by applying Kirchhoff 's Voltage Law around <u>meshes</u> excluding those that are part of <u>supermeshes</u> and supermeshes in the circuit
- **C81: Loop [current] analysis** develops equations for sufficient <u>loop currents</u> to solve a circuit (not necessarily planar) by applying <u>Kirchhoff 's Voltage Law</u> around sufficient loops.
- **C82:** A **linear circuit element** is a passive element or a dependent source where stimuli x_1 and x_2 acting alone produce responses y_1 and y_2 respectively, and stimulus $ax_1 + bx_2$ produces response $ay_1 + by_2$ where *a* and *b* are constants
- **C83:** A Linear circuit has <u>passive elements</u> (R, L, C) and <u>dependent sources</u> each of which are have <u>linear circuit elements</u>
- **C84:** The **Superposition Theorem** states that the unknown <u>voltages</u> or <u>currents</u> in a <u>linear circuit</u> with multiple <u>independent sources</u> may be calculated (using a method of choice) by setting all independent sources except one to zero in turn and summing the individual solutions; <u>dependent sources</u> are not set to zero

Further Waveform Definitions

Definitions in response to Q2 introduced the concept of a waveform (**C26**). Six specific waveforms that are frequently encountered in electric circuit analysis are defined in Table IX.

Table IX: What are typical waveforms encountered in circuits?

- **C85:** A step <u>waveform</u> has value of zero before an initial time and positive value after that time.
- **C86:** A **ramp** <u>waveform</u> has value of zero before an initial time and constant slope staring at zero at the initial time.
- **C87:** A **pulse waveform** is zero before a start time and after an end time and has a defined variation between these two times
- **C88:** A **unit impulse** occurring at a stated time is zero infinitesimally before and after the time of occurrence and has the property that its definite integral is unity
- **C88:** A sinusoidal waveform varies with time according to a sine or cosine function and is specified by three parameters: the amplitude (peak value), frequency (reciprocal of the period) and phase (the offset of the first zero crossing).
- **C89:** An exponential waveform has time variation defined by the function $\exp(-t/\tau)$

Question 6: Physical Origins of Capacitors and Inductors

Physical basis and behavior of capacitors

Table X defines concepts related to the capacitor as a circuit element and Fig. 8 maps these concepts. The structure of a capacitor is defined first. The physical processes are defined next: the external charging current creates a separation of charge between the plates resulting in a potential difference. The voltage-current characteristic follows. Properties of series and parallel capacitors as well as the capacitive voltage divider analogous to those for the resistor follow.

Two observed phenomena give rise to concept definitions. Voltage changes across capacitors are relatively slow while current can change instantaneously; hence the voltage flywheel concept. Under certain conditions a capacitor may have voltage across it but have zero current: the capacitor is then described as an open circuit.

Table X: Concept definitions for Question 6(a): What are the physical basis and behavior as circuit elements of (a) capacitors

- **C90:** A **capacitor** is a <u>circuit element</u> with structure consisting essentially of two sheets of <u>conducting material</u>, called plates, each connected to a terminal, separated by a sheet of <u>dielectric</u> material, normally of uniform thickness
- **C91:** Charging (and discharging) of a capacitance requires a <u>current</u> in an external circuit that adds <u>charge</u> to one plate and removes an equal and opposite charge from the other plate; while no current crosses the <u>dielectric</u>, the current entering one plate is equal and to the current leaving the other plate
- **C92: Charge stored in a capacitor** is equal to the charge deposited on one <u>plate</u> and is given by the integral of the <u>charging current</u>
- **C93: Electric field associated with a capacitor** is due to the equal and opposite <u>charges</u> resident in the <u>metallic plates</u> that collect at the interfaces with the <u>dielectric</u>
- **C94: Polarisation of the dielectric** is the distortion of the atoms in the dielectric as a result of the <u>electric field</u> crossing the dielectric, with electrons bound to atoms tending toward the positive plate and the positively charged atomic nuclei tending toward the negative plate
- **C95:** The **voltage across a capacitor terminals** is proportional to the <u>charge stored</u> and is also equal to the potential difference calculated from the <u>electric field</u>
- **C96:** Capacitance is the constant of proportionality (C) relating the <u>charge stored</u> in a capacitor to the <u>voltage between the plates (q=Cv)</u>
- **C97:** The **voltage-current characteristic** for a capacitor gives the current as proportional to the rate of change of voltage, the constant of proportionality being the capacitance, (i=Cdv/dt); there is the converse integral form v = (1/C) *idt*
- **C98:** Convention for voltage and charging current for a capacitor allows voltage and current directions to be defined arbitrarily; when actual values are obtained, they are interpreted consistently with a current actually positive into a terminal causing that terminal to increase in voltage relative to opposite terminal; a positively charged plate has the more positive potential
- **C99:** The **energy stored in a capacitor** is one half of the voltage squared times the capacitance and with an ideal dielectric can be returned to the external circuit without loss
- **C100: Capacitor as voltage flywheel** captures the fact that a change the <u>voltage</u> across a <u>capacitor</u> requires the transfer of <u>charge</u> and therefore cannot occur instantaneously; the only theoretical exception is if the current is an <u>impulse</u>
- **C101: Capacitor is effectively an open circuit** in a circuit that is in a steady state with constant valued voltage sources; this does not necessarily hold for constant valued current sources
- **C102: Capacitors** <u>in series</u> have an <u>equivalent</u> capacitance whose reciprocal is the sum of the reciprocals of the individual capacitance.
- C103: Capacitors in <u>parallel</u> have an <u>equivalent</u> capacitance equal to the sum of the individual capacitances
- **C104:** A **Capacitive Voltage Divider** is made up of two <u>capacitors</u> (<u>capacitance</u> C_1 and C_2) in series and has division ratio $C_2 (C_1 + C_2)$ where the output voltage is across C_1

Figure 8. Concept map for Question 6(a): What are the physical basis and behavior as circuit elements of (a) capacitors ...

Physical basis and behavior of inductors

Table XI defines concepts related to the inductor as a circuit element and Fig. 9 maps these concepts. Additional prior knowledge on magnetic phenomena is required as defined in Table XI. The structure of an inductor follows. The physical processes governed by the Laws of Faraday and Lentz are defined next. Inductance is introduced as a single property that represents the physical structure and its linking magnetic field when a current flows. The voltage-current characteristic follows. Properties analogous to those for the series and parallel resistors follow in differential and integral forms. As in the case of the capacitor, the inductor is viewed as a current flywheel and appears to be a short circuit when the current is constant.

- Table XI. Concept definitions for Question 6(b): What are the physical basis and behavior as circuit elements of (b)inductors?
- **PK: Magnetic forces** occur between any pairs of (i) naturally occurring or man-made permanent magnets, (ii) between current-carrying conductors and (ii) ferromagnetic objects magnetized by a current in a conductor. A **magnetic field** in the vicinity of a magnet or current carrying conductor is a representation of the spatial variation of the magnitude and direction of the <u>magnetic force</u> that would be experienced in the space. **Magnetic flux lines** are imagined lines in the vicinity of a source of magnetic force (permanent magnet or current in a conductor) that depict the direction and strength of the force; the stronger the field the closer the lines. Flux lines close on themselves. **Flux density** is a measure of the force due to a magnetic flux expressed in terms of the flux lines per unit area. **Electromagnetic induction** is the phenomenon of a voltage being produced (induced) between the terminals of a conductor when the flux linking the conductor changes with time
- **C110: An inductor** is a <u>conductor</u> formed into a single- or multi-turn closed shape or coil that in the ideal case has negligible resistance
- **C111:** A **current in an inductor** (the **magnetizing current**) gives rise to <u>magnetic flux lines</u> passing through the turns of the conductor
- C112: The flux linkages for an inductor is the sum of the flux lines linking each turn

- **C113: The voltage** induced in a <u>conductor</u> when the <u>flux linking</u> the conductor changes is, according to Faraday's Law, proportional to the time rate of change of the <u>flux linkages</u>
- **C114: Lentz's Law** states that the direction of the <u>voltage induced</u> in a <u>conductor</u> when the <u>flux</u> <u>linkages</u> change is such as would cause a <u>current</u> to flow in a direction that opposes the change of <u>flux</u>
- **C115:** The **inductance** or **self-inductance** of an <u>inductor</u> is the constant of proportionality (depending on the geometry, number of turns and surrounding medium), between the time rate of change of <u>current</u> in the <u>conductor</u> and the <u>induced voltage</u> across the conductor.
- **C116:** The **voltage-current characteristic of an inductor** is v = Ldi/dt where the conventions for v and i are consistent with Lentz's Law
- **C117: Convention for voltage and current** for an inductor allows voltage and current directions to be defined arbitrarily; when actual values are obtained, they are interpreted consistently with a voltage that is actually positive in the defined direction would give a current increasing relative to the defined direction
- **C118: Energy is stored in an inductor** when a current flows; the energy is equal to one half of the current squared times the inductance and may be returned to an external circuit if the inductor is ideal
- C119: An inductor is a linear circuit element if the flux linkages are proportional to the current in the inductor
- **C120:** A **real inductor** has a conductor with finite resistance which for analysis is in series with the inductance.
- C121: Ideal inductors connected in series have an equivalent inductance equal to the sum of the individual inductances
- **C122: Ideal inductors connected in parallel** have an equivalent inductance with reciprocal equal to the sum of the reciprocals of the individual inductances
- **C123: Inductor as current flywheel** expresses the fact that the current in an inductor cannot change instantaneously; the only theoretical exception is if the voltage is an <u>impulse</u>
- C124: An ideal inductor is effectively a short circuit if the current it carries is constant with time

Figure 9. Concept map for Question 6(b): What are the physical basis and behavior as circuit elements of ... (b)inductors?

Question 7: Transients in Circuits

When considering resistive circuits, independent sources may have time-dependent values and Ohms Law would be written v(t) = i(t)R. The voltage and current waveforms have the same shape. Responses when multiple sources have different waveforms are the superposition of the individual response waveforms. With capacitors and inductors present, their voltage-current relationships $i_C = Cdv_C/dt$ and $v_L = Ldi_L/dt$ (or their integral forms) in general give rise to different voltage and current waveforms. When resistors, inductors and capacitors are connected in a circuit with independent and possibly dependent sources, analysis and solution of the circuit must satisfy the principle of the circuit as a system (**C45**). The use of Kirchhoff's Voltage and Current Laws (**C46**, **C47**) in formulating circuit equations ensures compliance. The resulting equations are linear constant coefficient differential equations.

The context of interest is when a circuit with capacitors or inductors operating in an initial state (C130), experiences a disturbance (C131) in the form of a changed excitation or element. The circuit will move to a new steady state (C130). Such changes are described as transients (C132) and describing how voltages and currents change as the circuit moves to a new steady state.

Table XII defines a set of concepts for transient analysis of circuits and Fig. 10 presents a map of these concepts.

Table XII: Concept definitions for Question 7: What is the behavior and analysis method for circuits containing resistors, capacitors and inductors with time-varying sources or changes in circuit parameters or elements?

- **PK:** First and second order constant coefficient differential equations: solution method and related terms: forcing function, complete response as complementary function and particular integral.
- C130: A steady state in a <u>circuit</u> is the condition when all <u>voltages</u> and <u>currents</u> have <u>waveforms</u> that are constant or vary periodically
- **C131:** A **disturbance** in a circuit is a change such as: change to waveform of source(s), switching of source(s), a change in element parameter values or addition or removal of elements from the circuit
- **C132:** A **transient** in a circuit that includes <u>inductors</u> or <u>capacitors</u> is the time-varying process that exists due a <u>disturbance</u>
- **C133: The state of a circuit** with inductors or capacitors is the set of values of inductor current(s) and capacitor voltage(s)
- C134: The initial state of a circuit is the state at the start of a transient
- C135: The final steady state of a circuit is the <u>state</u> at the end of a transient, that is, when a <u>steady</u> <u>state</u> is reached
- C136: Kirchoff's Voltage and Current Laws are applied in circuits with elements including <u>inductors</u> or <u>capacitors</u> using their respective <u>voltage-current characteristic</u> resulting in one or more constant coefficient linear differential equation
- **C137:** A **first order circuit** has one (or its <u>equivalent</u>) <u>energy storage</u> element and is governed by a first order differential equation
- C:138: A second order circuit has two <u>energy storage</u> elements (or their <u>equivalents</u>) and is governed by a second order differential equation
- **C139:** The **natural response** of a circuit is the solution to the differential equation with the <u>forcing</u> <u>function</u> set to zero, corresponding to the mathematical term <u>complementary function</u>
- **C140:** The **forced response** of a circuit is the <u>steady state</u> response when the natural response has gone to zero, corresponding to the mathematical term <u>particular integral</u>
- C141: The complete response of a circuit is the sum of the <u>natural</u> and <u>forced responses</u>
- **C142:** The **time invariance principle** states that, given the solution to a differential equation x(t) when the forcing function is f(t), the solution with forcing function f(t-T) is x(t-T)
- **C143: The zero-input response** of a circuit is the solution when the circuit has initial energy storage but no source(s) providing a forcing function

C 144: The **zero-state response** of a circuit is the solution when source(s) provide a forcing function but the initial energy storage is zero

Question 8: Steady State Sinusoidal Analysis

The concept of a circuit in a steady state is introduced in **C130**. In the context of transient analysis. An important for of steady state is the steady state sinusoidal condition defined in **C150**. The set of concepts in Table XII extend the various circuit laws, theorems and rules established in response to Questions 3 to 5 to circuits containing resistors, inductors and capacitors in the sinusoidal steady state.

Two critical concepts are the phasor (**C151**) and impedance (**C155**). The phasor represents sinusoidal voltages and currents by complex numbers and dispenses with the need to use the frequency – which is constant - in equations for voltage and current. Concept **C151** allows values of the waveform to be calculated at any time from the waveform should this prove necessary. As in other cases, voltage and current conventions are essential (**C152**).

The second critical step is the description of individual passive circuit elements as impedances that embody their voltage-current characteristics under steady state sinusoidal conditions (at a fixed frequency). Networks of such elements, incorporating dependent sources as well, have equivalent impedances (**C157**) with the various forms analogous to the cases in resistive circuits: series, parallel and star and delta forms.

Extensions of Thevenin and Norton's Theorems extend to describe two terminal networks with steady state sinusoidal sources and impedances. The notions of source transformation follow as does the Maximum Power Transfer Theorem for the case of complex Thevenin impedance and load impedance.

Table XIII defines a set of concepts for steady state sinusoidal analysis of circuits and Fig. 11 presents a map of these concepts.

Table XIII: Concept definitions for Question 8: What is the behavior and analysis method for circuits containing resistors, capacitors and inductors under sinusoidal steady state conditions?

- **PK:** Complex numbers, rectangular and polar co-ordinates, arithmetic with complex numbers, Euler notation
- C150: <u>Steady state</u> sinusoidal conditions exist in a <u>circuit</u> if all <u>independent sources</u> have <u>sinusoidal waveforms</u> at a common <u>frequency</u> and element voltages and currents are sinusoidal, the circuit having been excited for sufficiently long for any <u>natural response</u> to have gone to zero
- **C151:** The **phasor representation** for a <u>sinusoidal waveform</u> having a known and constant <u>frequency</u> is a complex number with magnitude equal to the <u>amplitude</u> of the waveform and angle equal to the <u>phase</u> of the waveform; phasors obey the laws of arithmetic for complex numbers
- **C152:** The **sign convention associated with a phasor** voltage or current may be assigned arbitrarily; the voltage-current relationship for an element is written with the same sign on both sides of the equation if the current is shown entering the plus-marked terminal otherwise negative sign must be introduced on one side of the equation
- **C153: Capacitive reactance** is the ratio of the magnitude of the <u>phasor voltage</u> across a capacitor to magnitudes of the <u>phasor current</u>
- **C154: Inductive reactance** is the ratio of the magnitude of the <u>phasor voltage</u> across a capacitor to the magnitude of the <u>phasor current</u>
- **C155:** The **Impedance** or **complex impedance** of a single or network of <u>passive elements</u> with two terminals is the ratio of the complex <u>phasor voltage</u> across the terminals to the complex <u>phasor current</u> passing between the terminals
- **C156: Kirchhoff's Voltage and Current Laws** may be used to apply the methods of systematic and simplification analysis using <u>phasor</u> representations for voltages and currents and <u>impedances</u> in a circuit under <u>steady state sinusoidal</u> conditions
- **C157: The equivalent impedance** of a <u>network of passive circuit elements</u> and <u>dependent sources</u> with control variables completely within the network is a single impedance that may replace the network without affecting the behavior of an external circuit to which it is connected; the real and imaginary parts are the resistive and reactive components respectively
- **C158: Complex impedances in series** have a single <u>equivalent impedance</u> equal to the complex sum of the individual <u>impedances</u>
- **C159: Complex impedances in parallel** have a single <u>equivalent impedance</u> with reciprocal equal to the complex sum of the reciprocals of the individual <u>impedances</u>
- **C160: Star-Delta transformations** may be applied to three <u>impedances</u> connected in one form to obtain the equivalent form.
- **C161:** The **admittance** of an <u>element</u> or <u>equivalent circuit element</u> is the reciprocal of its <u>impedance</u>, with real part called conductance and imaginary part called susceptance
- **C162:** The **Thevenin equivalent** of a <u>two-terminal network</u> under <u>steady state sinusoidal</u> <u>conditions</u> is a <u>voltage source</u> with value expressed as a <u>phasor</u> in series with an <u>impedance</u>
- **C163:** The **Norton equivalent** of a two-terminal network under <u>steady state sinusoidal</u> conditions is a current source with value expressed as a phasor in parallel with an impedance
- C164: Source transformations are valid under steady state sinusoidal conditions
- C165: The voltage divider law for two complex impedances is analogous to that for resistors.
- **C166:** The **current divider law** for two complex impedances is analogous to that for resistors.
- C167: The instantaneous value of a voltage or current may be recovered from the <u>phasor</u> representation at time *t* by projecting the tip of the phasor located at angle $2\pi ft + \theta$ onto the horizontal axis for a cosine waveform and onto the vertical axis for the sine waveform with frequency *f*
- **C168:** The **maximum power transfer theorem under steady state sinusoidal conditions** states that maximum power is delivered by a source to a load impedance when the load impedance is equal to the complex conjugate of the Thevenin impedance of the source
